Assignment 10.1

Scott Breitbach

8/3/2020

Title: DSC520 Final Project: Effect of Home Cornhusker Games on Public Safety

Section 1: Getting Started

Introduction:

Lincoln, Nebraska is the home of the Cornhuskers and every fall, Husker football is a huge draw to the city of Lincoln. When there are home football games, Memorial Stadium, which has a seating capacity of 85,458 and has sold out the last 375 games, essentially becomes the third largest city in Nebraska.

In a city of just under 300,000 people, I would like to see what impact, if any, this huge influx of people has on public safety, including crime and traffic incidents.

Research questions:

- 1. Does crime increase on Husker game weekends compared to non-game weekends?
- 2. Do traffic incidents increase on game weekends compared to non-game weekends?

If yes to 1 or 2:

- Which day of the week has the largest change from baseline?
- Does game time have an impact (morning or evening game)?
- Is there a difference in before-game vs after-game?
- Does the opposing team have an impact?
- Is there an opposite effect on away-game weeks when many people travel to watch the game?

Approach:

I plan to look at several years of crime and traffic data (at least 2017-2019) as well as Husker football game date and time information to generate crime and traffic incident baselines for non-Husker home game weeks and compare the baselines to Husker home game weeks to evaluate for any effect.

How your approach addresses (fully or partially) the problem:

This approach will be exploratory in nature, in an effort to determine whether there is a corresponding increase in crime and traffic incidences alongside the increase in individuals to the city.

Data:

All of my datasets were obtained through the Open Data and Performance Management page for the city of Lincoln.

Files:

- LPD 2013 2020 Arrests and Citations De Coded.csv
- LPD 2017 2020 Incident Reports.csv
- LPD Traffic Crashes 2013 2020.csv

I may also look at Traffic Stops, though those .csv files are compiled by individual year.

All data was created by the Lincoln Police Department and compiled via the LPD Records Management System. The Incident Report data has 25 variables and 116,263 observations. When loading this dataset, there were 50 parsing failures, so I will have to investigate and see if I can solve the issue, or just exclude those data points if I can't. The Traffic Crashes data has 18 variables and 24,500 observations, and the Arrests and Citations data has 366,000 observations of 18 variables.

Many of the variables are meaningless to me, but I will primarily be looking at total incidences and the dates and times on which they occurred. I will also need to find or generate my own dataset with the dates and times of the Cornhusker football games, whether they were home or away, and who they played. I will also need to convert to a common date time format between files in order to perform the analysis.

Required packages:

I will need the following packages

- readr
- ggplot2
- lubridate
- dplvr
- hmisc
- car

I will probably add more as I need them.

Plots and table needs:

I will need a chart of incidents over time (perhaps by week) could be useful to illustrate whether there are spikes on game weeks. If there is an increase in incidents on game weeks, bar charts showing the average increase by opposing team, day of the week, pre- or post-game, or any other correlations that reveal themselves during analysis.

Questions for future steps:

I probably have all of the tools I need, though I'm sure I will need a refresher on some of the steps along the way, especially when it comes to converting dates to a common format as well as a way to compare the date ranges between datasets.

One thing that I would like to learn more about is creating my own functions, so perhaps I will get a chance to do that within the scope of this project.

Section 2: Cleaning Your Data and Exploratory Data Analysis

```
# Load game data

Section 3: Final Project Submission

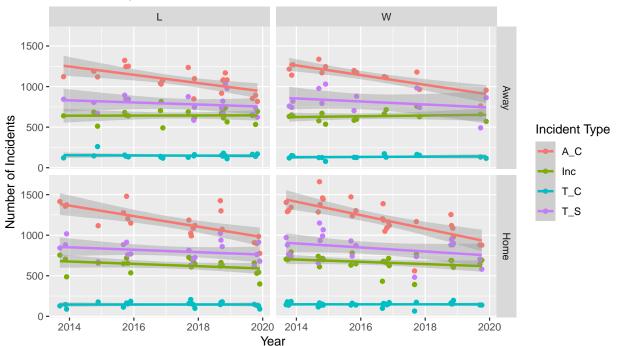

NOTE: the variables for the Public Safety data are defined as follows:

- A_C: Arrests and Citations
- Inc: Incident Reports completed
- T C: Traffic Crashes reported
- T_S: Traffic (and Pedestrian) Stop records

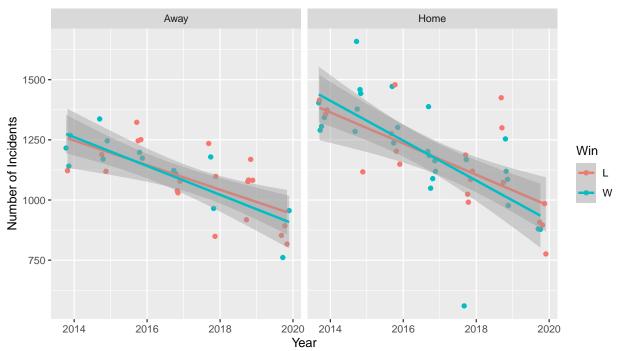

Once I had my data cleaned, I still needed to work with some of the data in different ways. To that end, I made a couple of other data frames. In one, H_G.long, I took the Public Safety totals that I had added to my Husker Games data set from each category and "melted" them into just two columns, represented by "variable" and "value". This helped in creating charts that included all four categories instead of working with them individually.

The other data set I created from my Husker Games data set by converting some of the character variables, such as Location (Home/Away) and Win (W/L) to 1's and 0's so that I could run correlation with them. Once I had those set up, I started playing around with different ways to visualize and explore the data:

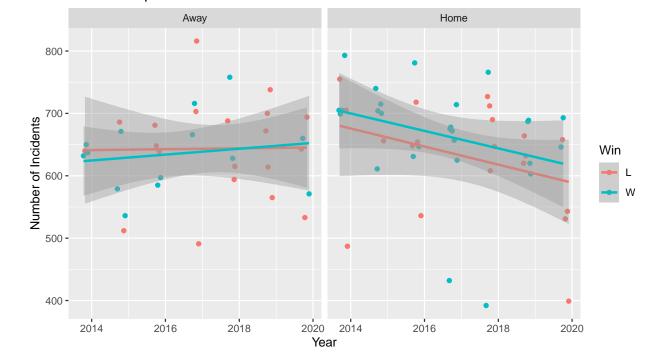

Public Safety Incidents Over Time

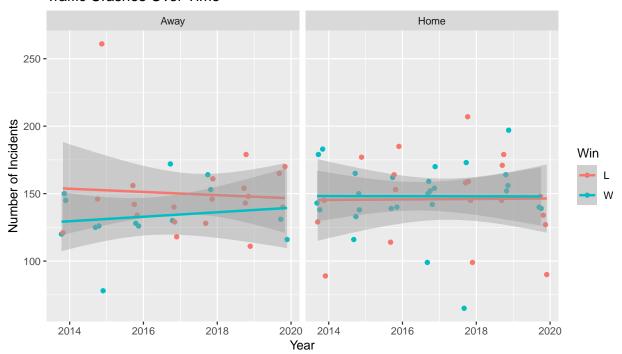

Arrests and Citations Over Time

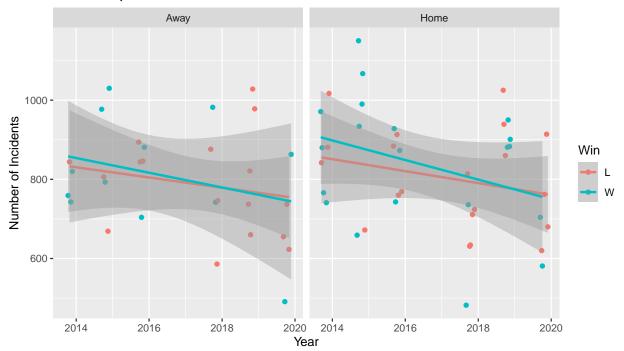

Incident Reports Over Time

Traffic Crashes Over Time

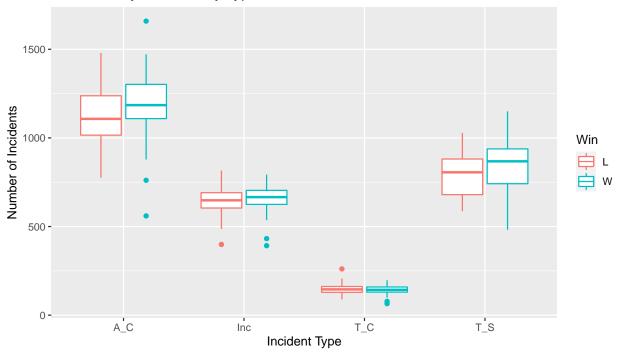

Traffic Stops Over Time

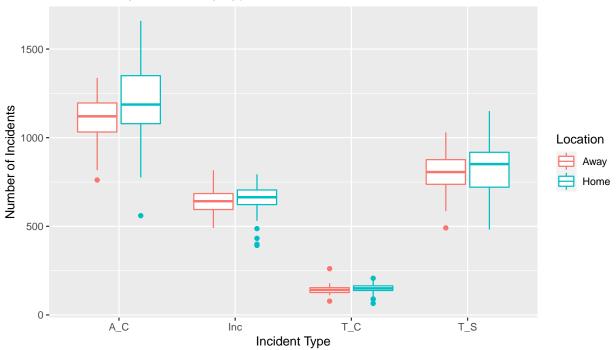

The first chart, with all four variables shows that for both Wins and Losses, Home and Away games, that Public Safety incidents are either generally remaining steady or decreasing over time, which is good news!

The remaining four charts compare Win and Loss data by date, faceted by Location. With the exception of "Incidents" at home games, all of the Win and Loss lines are either crossing or converging, indicating that whether the Huskers win or lose might not have much of an impact on Public Safety.

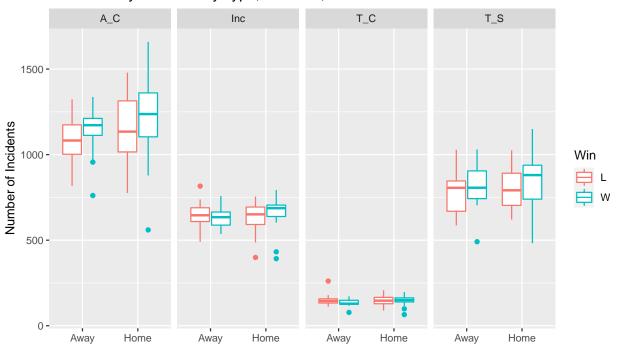

Public Safety Incidents by Type and Outcome

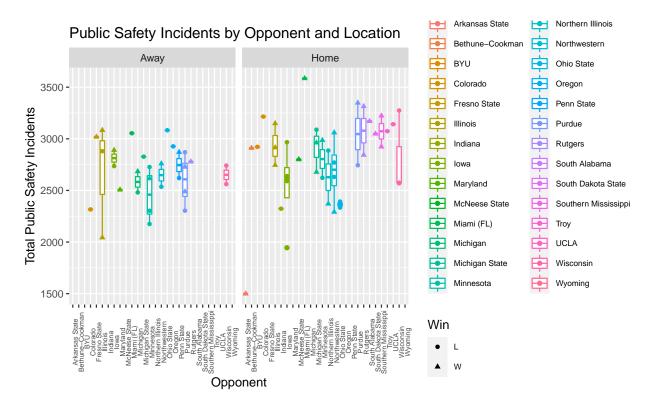

Public Safety Incidents by Type and Location

Public Safety Incidents by Type, Location, and Outcome

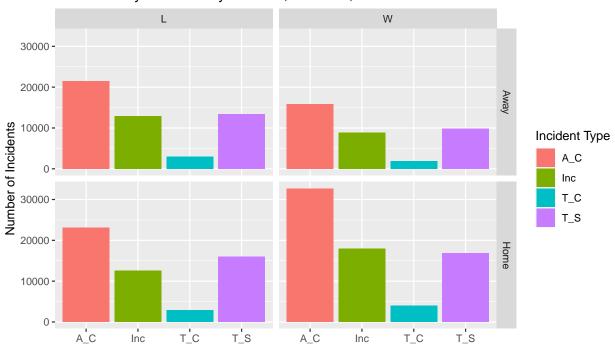

Public Safety Incidents by Opponent Opponent Arkansas State Northern Illinois 3500 -Bethune-Cookman Northwestern Ohio State Total Public Safety Incidents Colorado Oregon 3000 Penn State Fresno State Purdue Illinois Indiana Rutgers 2500 South Alabama Iowa South Dakota State Maryland 2000 -McNeese State Southern Mississippi Miami (FL) Troy Michigan UCLA 1500 Michigan State Wisconsin Minnesota Wyoming Opponent

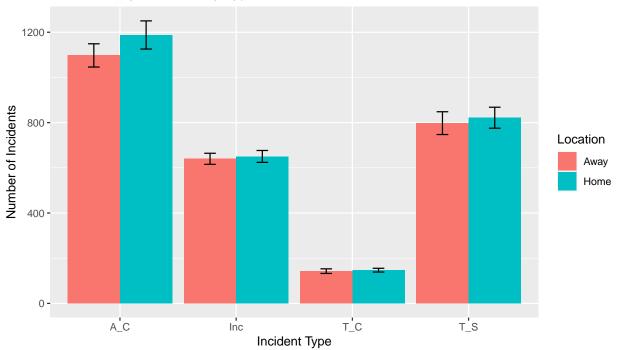

Looking at the boxplots, you can see that for most of the Public Safety variables it doesn't appear to make much difference whether it is a Home or Away game, or whether it is a Win or a Loss. The exception to this appears to be Arrests and Citations, which is slightly higher for both Wins and Home games.

Looking at the different Opponents, it appears that Miami is the clear leader when it comes to total number of Public Safety Incidents. This appears to largely be accounted for in the single data point for Away games, where it lies as a lone point above all of the others. The one Home game against Miami isn't the highest, but does look to be in the top three. There are only two data ponts, but perhaps this could be something to look into further.

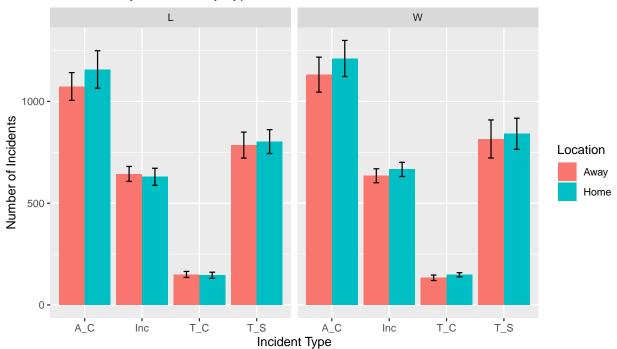

Public Safety Incidents by Variable, Location, and Outcome

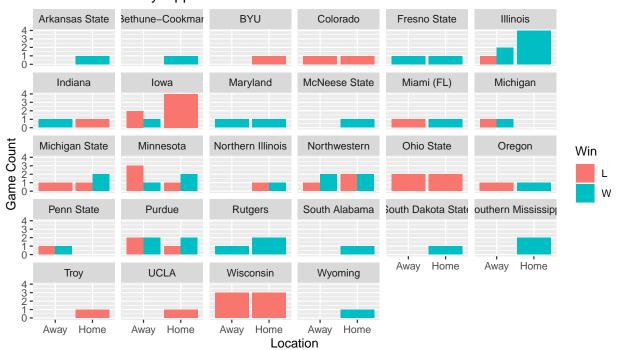

Public Safety Incidents by Type and Location

Public Safety Incidents by Type, Location, and Outcome

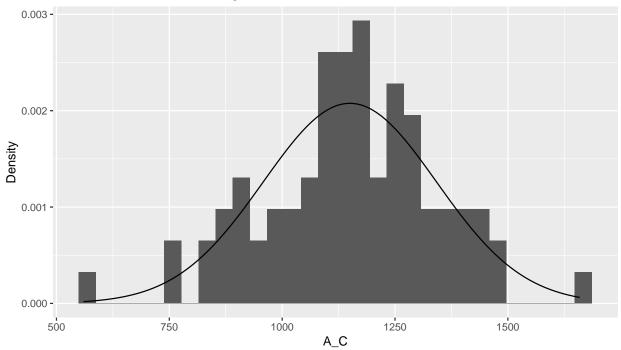

Game Outcome by Opponent and Location

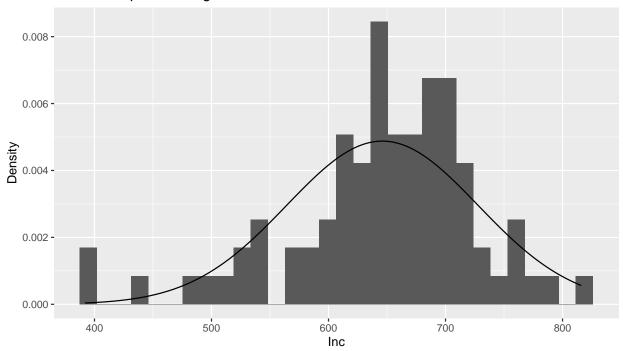

These bar charts provide another way to compare number of Public Safety incidents by type and both Location and Outcome. I have added some error bars and again Arrests and Citations seems to be determined by Location more than the other variables. The last bar chart is just for fun, showing how the Huskers fared against their Opponents in both Home and Away conditions.

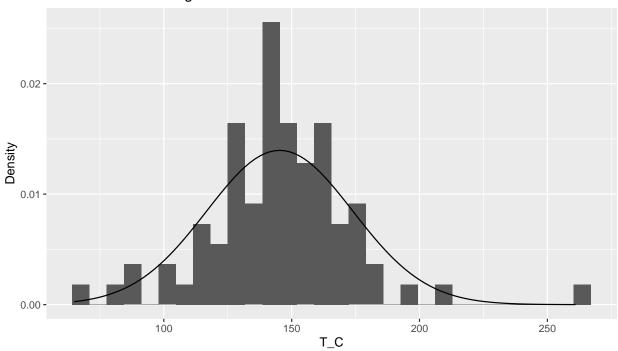

Arrests and Citations Histogram

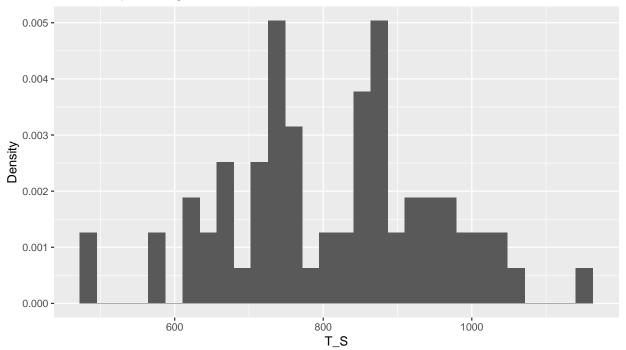

Incident Reports Histogram

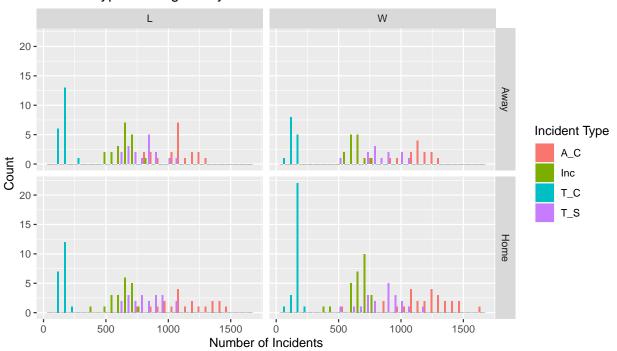

Traffic Crashes Histogram

Traffic Stops Histogram

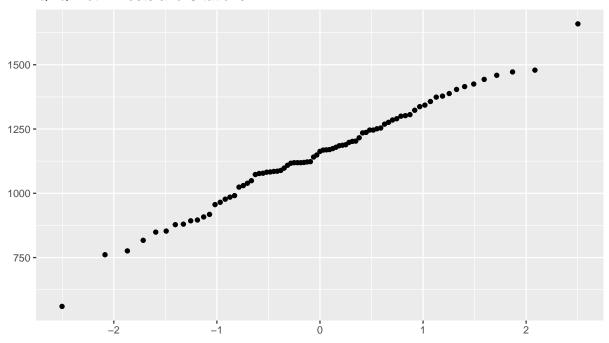

Incident Types Histogram by Outcome and Location

Overall the distributions of each Public Safety Incident Type appear fairly normal, which they should, considering each sample set is over 10,000 observations, however the Incident Reports Histogram does look slightly skewed and the Traffic Stops Histogram looks like it might be bimodal. The last histogram shows that the histograms for each Incident Type look pretty similar regardless of Location or Outcome.

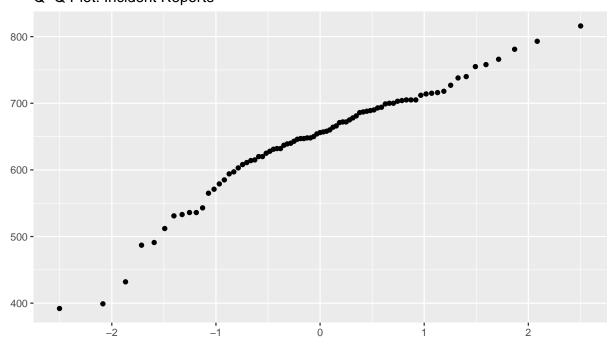

```
## Check for normal distribution
shapiro.test(Husker_games$A_C) # 0.8052
##
    Shapiro-Wilk normality test
##
##
## data: Husker_games$A_C
## W = 0.99026, p-value = 0.8052
shapiro.test(Husker_games$Inc) # 0.001708 <- not normal</pre>

##
##
    Shapiro-Wilk normality test
##
## data: Husker_games$T_S
## W = 0.9908, p-value = 0.8965
# Check for normalcy w/ qq plot
qplot(sample = Husker_games$A_C) + labs(title = "Q-Q Plot: Arrests and Citations")
```

Q-Q Plot: Arrests and Citations

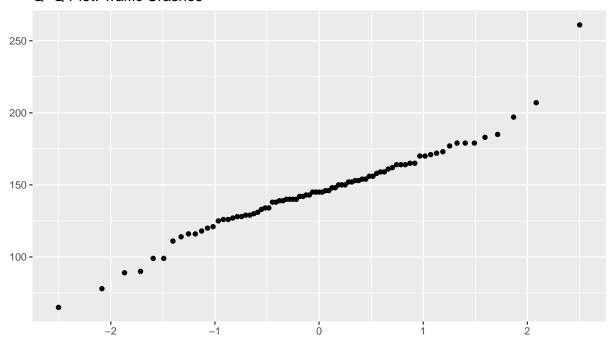

qplot(sample = Husker_games\$Inc) + labs(title = "Q-Q Plot: Incident Reports")

Q-Q Plot: Incident Reports

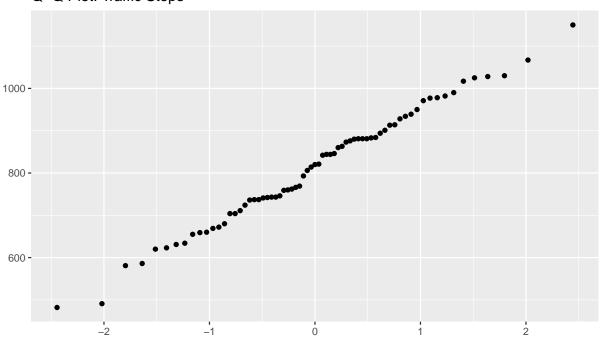

qplot(sample = Husker_games\$T_C) + labs(title = "Q-Q Plot: Traffic Crashes")

Q-Q Plot: Traffic Crashes

The Shapiro-Wilk normality tests show that the Arrests and Citations and the Traffic Stops Public Safety Incident Types have a fairly normal distribution, while the Incident Reports and the Traffic Crashes have a distribution that is not normally distributed. This is also reflected by the Q-Q plots for each.

Checking correlations between each Public Safety Incident Type with both Location and game Outcome, I found that Arrests and Citations was the only Incident Type that had a significant correlation and that was with Location. Arrests and Citations with game Outcome and Total number of Incidents with both Location and Outcome all had a significance around 0.1, but I suspect the correlation of Total Incidents is largely an artifact of the Arrests and Citations data set, which accounts for around 40% of the total data.

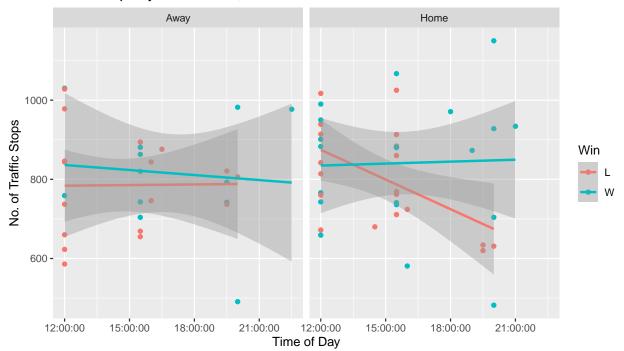

Looking at the R-squared values, we see that the some of the Public Safety Incident Types correlate pretty well with each other. Ignoring Total Incidents for a moment, we see that Arrests and Citations correlates really quite well with Traffic Stops, sharing 53% of variability. Traffic Stops and Incident Reports are the next highest, with 13%. However, we are more interested in how these Incident Types correlate with game Location (Home or Away) and game Outcome (Win or Lose) and unfortunately, while Arrests and Citations comes in at the highest for both, it only accounts for 5.5% and 3.2% of variability with Location and Outcome respectively and as we saw, only the correlation with Location is significant.

Interestingly, Location and Outcome share 2.6% of their variability, so it appears there may be some truth to Home team advantage.

Arrests and Citations by Game Time, Location and Outcome

Traffic Stops by Game Time, Location and Outcome

Looking at the two variables that had normal distribution curves, I did notice something interesting and that's that, while the number of incidents for Away games remain fairly constant regardless of game time and also for Home games, if the Huskers Win, but if the Huskers lose, the number of Incidents starts higher in the morning and drops dramatically throughout the day for later games. I suspect it may have something to do with people being tired and ready to go home after later games when the Huskers lose, compared to being in a celebratory mood and staying out if they win.

Doing some modeling based on Opponents and Location may help to give an indication as to what to expect for different types of incidents. Here I have just used the Arrests and Citations data, but more in-depth analysis could be done for each Opposing team and each Incident Type.

My goal with this project was to determine what effect, if any, the influx of people with a Home Cornhusker football game would have on the overall crime rate in Lincoln and while I found there is a slight increase in Arrests and Citations, overall I found relatively little effect. All the same, the data could be useful (perhaps moreso by including additional years of data) in predicting increases in Police coverage, especially when particular Opponents are accounted for.

The most uplifting I found was that crime appears to continue on a downward trend year-to-year and I hope that this trend continues for the forseeable future. Also, Go Big Red!
